Day 11 – Reactive Forms and Basic Authentication Implementation

1. Objective of the Day

The objective of the day was to implement a structured login system using Angular Reactive Forms and understand form handling and validation at a basic level.

2. Tasks Performed

- Designed a login form with fields: username, email, and password
- Implemented the form using Angular Reactive Forms
- Defined form structure and controls in TypeScript
- Applied basic validation rules such as required fields and minimum length
- Implemented email format validation
- Displayed validation error messages based on form state
- Disabled submit button when form was invalid
- Handled form submission through component logic
- Introduced the concept of authentication flow

3. Tools / Technologies Used

- Angular Framework
- TypeScript
- Reactive Forms Module

4. Key Learnings

- Reactive Forms provide better control over form structure and validation
- Form logic should be handled in TypeScript, not in templates
- Angular validators ensure data correctness
- Form state (valid/invalid) controls user interaction
- Structured forms improve scalability and maintainability

5. Challenges Faced

- Understanding Reactive Forms structure and syntax
- Handling validation messages correctly

6. Solutions

- Practiced building forms step-by-step
- Used Angular validators to simplify validation logic

7. Conclusion

- Successfully implemented a structured login form
- Gained a strong understanding of Reactive Forms and validation
