Day 7 – Dependency Injection and Angular Services

1. Objective of the Day

The objective of the day was to understand the concept of dependency injection in Angular and learn how to use services for managing shared data and application logic.

2. Tasks Performed

- Revised remaining template control flow concepts such as @switch, @case, and @default
- Implemented multiple condition handling using @switch
- Used @empty block to handle empty list scenarios
- Studied the concept of dependency injection (DI) in Angular
- Understood how Angular provides dependencies instead of creating them manually
- Learned the importance of decoupling components from logic
- Created a service using Angular CLI
- Implemented reactive state inside the service using signals
- Injected the service into a component using constructor injection
- Accessed and displayed service data in the template
- Updated UI automatically through service state changes

3. Tools / Technologies Used

- Angular Framework

- TypeScript
- HTML

4. Key Learnings

- Dependency Injection helps manage shared dependencies efficiently
- Services are used to store reusable logic and shared state
- Angular automatically creates and injects service instances
- Components should not create services manually
- Signals inside services enable reactive UI updates
- @switch and @empty enhance template readability

5. Challenges Faced

- Understanding dependency injection concept at a deeper level
- Differentiating between component logic and service logic

6. Solutions

- Studied DI concept with real-world analogies
- Practiced creating and injecting services multiple times

7. Conclusion

- Successfully implemented services with dependency injection
- Achieved clear separation of concerns between UI and logic
